(54) Title: APPARATUS, AND ASSOCIATED METHOD, FOR INTEGRATING OPERATION OF PACKET RADIO COMMUNICATION SYSTEMS

(57) Abstract: Apparatus, and an associated method, forms an integrated packet radio communication system. An integrated system (16) is formed of portions of a GPRS system as well as portions of a WLAN system, such as that defined in the IEEE 802.11 standard. A WIP (WLAN Integrated Protocol) layer (52, 92) is defined, functionally positioned between upper-level, GPRS layers (54, 94) and lower-level, WLAN layers (62). Advantages of a GPRS system as well as advantages of the WLAN system are maintained in the integrated system.

WO 01/99466 A2

APPARATUS, AND ASSOCIATED METHOD, FOR INTEGRATING
OPERATION OF PACKET RADIO COMMUNICATION SYSTEMS

The present invention relates generally to a
5 manner by which to integrate operation of packet radio
communication systems to form an integrated
communication system therefrom. More particularly,
the present invention relates to apparatus, and an
associated method, by which to combine operation of a
10 first packet radio system, such as a WLAN (Wireless
Local Area Network) defined pursuant to the IEEE
802.11 standard, with a second packet radio system,
such as a system which provides for GPRS (General
Packet Radio Service). Through operation of an
15 embodiment of the present invention, advantages of a
WLAN, such as high data rates and relatively
inexpensive infrastructure, is provided while also
providing global mobility and high security of a GPRS
system.

20 BACKGROUND OF THE INVENTION

Usage of multi-user radio communication systems
has become widely popular in recent years.
Advancements in communication technologies have
permitted the implementation, and portable
25 utilization, of such communication systems, thereby to
permit large numbers of users to communicate
therethrough.

A radio communication system, similar to other
types of communication systems, is formed of a sending
30 station and a receiving station interconnected by way
of a communication channel. In a radio communication
system, a radio communication channel forms the

communication channel. A radio communication channel is defined upon a portion of the electromagnetic spectrum.

In contrast, a communication channel defined in a wireline communication system is defined upon a wireline connection extending between the sending and receiving stations. Because a radio communication channel, defined upon a portion of the electromagnetic spectrum, is used to communicate data between the sending and receiving stations in a radio communication system, the need for a wireline connection to interconnect the sending and receiving station, required in a wireline communication system, is obviated. The mobility of communications in a radio communication system is inherently greater than that permitted in a typical wireline communication system.

Digital communication techniques have been implemented in radio, as well as other, communication systems. Digital communication techniques generally permit the communication system in which the techniques are implemented to achieve greater communication capacity than the capacity permitted in a communication system utilizes conventional, analog communication techniques.

A cellular communication system is exemplary of a communication system which is widely utilized and which regularly is constructed to make use of digital communication techniques. Communications in a cellular communication system generally are effectuated by way of mobile station carried by a user. A mobile station is a radio transceiver

permitting two-way communication of radio signals with network infrastructure of the cellular communication system. The network infrastructure of the cellular communication system is connected, for instance, to a
5 PSTN (Public-Switched, Telephonic Network), thereby to permit communication between the mobile station and a remote station, coupled to the PSTN.

A cellular communication system generally is operable over a fairly large geographical region,
10 sometimes national or even extra-national in scope. A user of the mobile station is able to communicate by way of the cellular communication system when located at virtually any location encompassed by the cellular communication system. And, as the user, together with
15 the mobile station, travels, handover of communications through successive portions of the network infrastructure of the cellular communication system permits continued communications by way of the mobile station.

20 At least one cellular communication system, the GSM (Global System for Mobile communications) cellular communication system includes the possibility that packet radio services pursuant to GPRS (General Packet Radio Service) shall permit the communication of
25 digital data, packetized into packets of data. Communication of packet data pursuant to GPRS is effectuated at the same level of security, QoS (Quality of Service) level, and global mobility, as that provided for conventional GSM, cellular
30 communications. Conventional proposals for GPRS messaging, however, permit only relatively low data communication rates for multimedia services, particularly when large numbers of users use the

system to effectuate conventional cellular communications. Installation of a GPRS system is also relatively costly.

Digital communication techniques are also
5 utilized in conventional LANs (Local Area Networks). LANs conventionally interconnect groups of computer work stations within an office area, or the like, to permit communications therebetween. Wireless networks, operable in manners analogous to wired LANs,
10 referred to as WLANs (Wireless Local Area Networks), have also been developed and are utilized to communicate data over a radio link. Some of such systems are able to provide for voice, as well as nonvoice, communications.

15 One system, standards of which are set forth in the IEEE 802.11 specification, provides for voice communications in a WLAN. A WLAN system constructed pursuant to the IEEE 802.11 standard provides a relatively quick data rate to effectuate communication
20 of data as well as a relatively simple infrastructure. However, in contrast to GPS systems, lessened security provisions are implemented. Additionally, a WLAN inherently does not provide wide-area mobility. If a manner could be provided by which to integrate
25 operation of a GPRS system and a WLAN system, incorporating the advantages of each, the resultant, integrated system would advantageously provide an improved communication system.

It is in light of this background information
30 related to radio communication systems that the significant improvements of the present invention have evolved.

SUMMARY OF THE INVENTION

The present invention, accordingly, advantageously provides apparatus, and an associated method, by which to integrate operation of packet
5 radio communication systems to form an integrated system.

In one aspect of the present invention, a manner is provided by which to combine operation of a first packet radio system, such as a WLAN (Wireless Local
10 Area Network) defined pursuant to the IEEE 802.11 standard with a packet radio communication system, such as a system which provides for GPRS (General Packet Radio Service). A resultant, integrated system is provided therefrom. Through operation of
15 various embodiments of the present invention, data transport and mobility management are both provided for in the integrated system.

A WLAN system constructed to comply with the parameters set forth in the IEEE 802.11 standard
20 provides for the communication of packet data at relatively quick data rates and requires the use of only relatively simple infrastructure installations. And, a GPRS system constructed to comply with the parameters set forth in an appropriate GPRS standard
25 provides for the communication of packet data in a manner which provides relatively high levels of security pursuant to a QoS (Quality of Service) structure, while also maintaining high levels of mobility of communications as a GPRS system is
30 generally installed in over a large geographical area. A WLAN system, in contrast, fails to provide wide-area mobility, security, and QoS support provided in a GPRS

system. And, a GPRS system requires relatively costly infrastructure investments while providing relatively low data rates. Generally, the advantages inherent in a WLAN system are also the disadvantages of a GPRS system, and the advantages of a GPRS system are also the disadvantages of a WLAN system. The integrated system provided for through an embodiment of the present invention advantageously makes use of the advantageous aspects of both the WLAN and GPRS system, thereby to provide an integrated system of improved characteristics.

In one aspect of the present invention, the communication system is defined in terms of logical layers. The integrated system of an embodiment of the present invention includes a logical layer, referred to as a WIP (WLAN Integration Protocol) layer positioned between lower layers and upper-level layers. The lower layers are formed of existing layers defined in the WLAN protocol, and the upper-level layers are formed of existing logical layers defined in the GPRS protocol. The WIP layer integrates the layers defined in the separate systems so that data generated by an upper-level layer is communicated through the lower-level layers in a transparent manner while maintaining the operational features of communications in the separate communication systems.

In another aspect of the present invention, a WIP layer is provided at a mobile station operable in a packet radio communication system constructed pursuant to an embodiment of the present invention. The WIP layer is positioned between upper-level, GPRS-

compliant layers and lower-level, WLAN-compliant layers.

In another aspect of the present invention, an interworking element (IWE) is provided as an interface
5 between structure of a WLAN and structure of a packet data network. The IWE is defined in terms of logical layers, and lower-level, WLAN-compliant layers.

In one implementation, the interworking element is formed of a modified SGSN (Serving GPRS Service
10 Node). The interworking element is coupled by way of an Ethernet hub to a series of access points, defined in the WLAN system. Functional operation of the WIP layer provides for mobility management in the integrated GPRS-WLAN system. Functions such as cell
15 ID mapping, cell ID acquisition, paging, communication of messages needed for such functions, and PDU definitions, identifier mapper within the WIP protocol, and suspend/resume service function, are all provided through operation of the WIP layer of an
20 embodiment of the present invention.

In these and other aspects, therefore, the present invention provides an integrator, and an associated method, for a packet radio communication system for communicating packet data. The integrator
25 integrates operation of a first packet data system having at least a first packet-data-system element with operation of a second packet data system having at least a second packet-data-system element, thereby to form an integrated system of the packet radio
30 communication system. An integration element is at least functionally coupled between the first packet-data-system element and the second packet-data-system

element. The packet data of any selected information-element type is of a plurality of element types defined in either of the first packet data system and the second packet data system.

5 A more complete appreciation of the present invention and the scope thereof can be obtained from the accompanying drawings, which are briefly summarized below, the following description of the presently-preferred embodiment of the invention, and
10 the appended claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 illustrates a functional block diagram of a packet radio communication system in which an embodiment of the present invention is operable.

15 Figure 2 illustrates a logical layer diagram showing portions of the integrated communication system forming a portion of the communication system shown in Figure 1.

Figure 3 illustrates a message sequence diagram
20 representing signaling associated with data transfer during operation of the integrated communication system portion shown in Figure 2.

Figure 4 illustrates a message sequence diagram representing signaling generated during operation of
25 the integrated communication system portion shown in Figure 2 during WLAN association operations and cell ID operations.

Figure 5 illustrates a message sequence diagram representing signaling generated during operation of

an embodiment of the present invention during the performance of paging operations.

Figure 6 illustrates a message sequence diagram representing signaling generated during operation of an embodiment of the present invention in which a mobile station requests a suspension of data transfer.

Figure 7 illustrates a message sequence diagram representing signaling generated during operation of an embodiment of the present invention in which the mobile station requests resumption of communication of packet data with the mobile station.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring to Figure 1, a communication system, shown generally at 10, is operable to provide radio packet service with a mobile station, such as any of the mobile stations 12. In the exemplary implementation, a two-way communication of packet data is provided. That is to say, forward-link packets of data are transmitted to the mobile station and reverse-link packets of data are sent by the mobile station, both by way of radio links 14.

The mobile stations 12 are capable of movement, such as their carriage by a user. While initially positioned at a first location, a mobile station may thereafter be repositioned to be located at a second location, all within a geographical area encompassed by fixed infrastructure of the communication system.

Here, the fixed infrastructure is divided into two portions, a first portion 16 and a second portion 18. The first portion 16 is formed pursuant to an

embodiment of the present invention, here an integrated system formed of a GPRS system and a WLAN system integrated theretogether. And, the second portion 18 is formed of a conventional GPRS system.

5 Both the first and second portions 16 and 18 coupled to a GGSN (Gateway GPRS Service Node) 22 which, in turn, is connected to an IP (Internet Protocol), or other packet data, network 24.

The conventional GPRS system formed of the second
10 portion 18 includes a plurality of Base Transceiver Stations (BTSs) 26. Each of the base transceiver stations defines a coverage area, or cell, within which radio links with mobile stations 12 are formable and between which handover of communications are
15 effectuable as a mobile station moves through successive coverage areas during a communication session. Sets of the base transceiver stations are coupled to base station controllers 28 which are operable, in conventional manner, to control operation
20 of the base transceiver stations. And, in turn, sets of the base station controllers are coupled to SGSNs (Serving GPRS Service Nodes) 30. Each SGSN is coupled to the GGSN 22. The GPRS system is operable pursuant to an appropriate GRPS standard to communicate packet-switched data between a mobile station 12 and another
25 communication station. The GPRS system is, for instance, constructed together with a GSM (Global System for Mobile Communications) cellular communication system in which communication stations
30 must be authenticated prior to permission to communicate by way of the communication system. A high level of security is thereby provided in

communications pursuant to a conventional GPRS or GSM-GPRS communication system.

The GPRS communication system portion 16 constructed pursuant to an embodiment of the present invention includes a plurality of spaced-apart access points 36 positioned throughout an area to be encompassed by the system portion 16. Each of the access points 36 defines a coverage area within which radio links 14 are formable with mobile stations 12 and pursuant to which communications are effectuable. The access points are connected to one another by way of lines 18 and to, here, an Ethernet switching hub 42. The Ethernet switching hub, in turn, is coupled to an IWE (Interworking Element) 44. And, the IWE 44 is connected to the GGSM 22. During a communication session, packet-switched communications are permitted with a mobile station 12. Here, the communications are effectuated over the radio links 14 in manners set forth in the IEEE 802.11 standard, or the like.

The integrated system of which the portion 16 is formed includes advantageous features of both the GPRS and the WLAN systems. Because communications over the radio links 14 are made in conformity with the WLAN standard, the high data rates and low infrastructure costs associated with the WLAN system are maintained. And, as other features of the GPRS system are maintained, the integrated communication system portion 16 provides the advantages of both a WLAN system and the GPRS system.

The IWE 44, as well as the construction of the mobile station 12, provides for the integration of the WLAN and GPRS systems. The functional positioning of

the IWE in the Figure between the Ethernet switching hub 42 and the GGSN 22 is exemplary. Alternately, a fixed-site radio transceiver could be modified to perform the functions of the IWE. Alternately, in
5 other implementations, the integrated communication system portion could include elements of the fixed network infrastructure of a conventional GPRS system in which the functionality of the IWE is embodied in a base transceiver station, a base station controller,
10 or a SGSN of such a system. Also, the functionality of the IWE could be embodied in an access point 36, or distributed amongst several access points.

Figure 2 illustrates the first communication system portion 16 in logical-layer form. Here, a
15 single mobile station 12 is represented, and also a single access point 36 of the fixed network infrastructure of the communication system portion is also represented. And, the Ethernet switching hub 42 and the IWE 44 of the fixed infrastructure of the
20 communication system portion is again illustrated in the Figure.

The mobile station 12 includes a logical layer, a WIP (WLAN Integration Protocol) layer 52 positioned between upper-level layers 54, 56, and 58, and lower-
25 level layers 62 and 64. The layers 54-58 form LLC, SNDCP/GMM, and IP layers, all as defined pursuant to an appropriate GPRS standard. And, the layers 62 and 64 form WLAN MAC and WLAN PHY layers, respectively. The layers 62 and 64 are functionally operable as
30 described in the IEEE 802.11 standard.

The access point 36 includes WLAN PHY and WLAN MAC layers 66 and 68, respectively, corresponding to

the layers 64 and 62 of the mobile station. The access point is further shown to include Ethernet MAC and Ethernet PHY layers 72 and 74 functionally connected by way of a relay 76.

5 The Ethernet switching hub 42 includes an Ethernet PHY layer 78 and an Ethernet MAC layer 82 as well as a relay function 84. And, the interworking element 44 also includes an Ethernet PHY layer 86 and Ethernet MAC layer 88 corresponding to the layers 78
10 and 82. A WIP logical layer 92 of an embodiment of the present invention is also shown to form a portion of the interworking element. The layer 92 is positioned between the lower-level layers 86 and 88 and upper-level layers 94 and 96. The layer 94 forms
15 a LLC layer, and the layer 96 forms a SNDCP/GMM layer. The interworking element also includes a GTP layer 102, a UDP/TCP layer 104, an IP layer 106, and L2 and L1 layers 108 and 112.

Because the upper-level layers correspond to GPRS
20 functional layers, the mobility management, authentication, security, user data encryption, and user data compression all provided pursuant to operation of such upper-level layers are again provided in the integrated system. On the radio
25 interface 14, the GPRS LLC, and higher, layers are again utilized in the integrated system while the lower-level layers correspond to the layers of a WLAN system by which to transmit signaling and user data.

The WIP layers 52 and 92 provide for the
30 performance of various functions, including the relaying of packet data between the upper-level layers and the lower-level layers. Additionally, the WIP

layers provide for the transport of TLLIs (Temporary Logical Link Identifiers) and to insert a cell identifier into uplink data.

A message sequence diagram, shown generally at 5 114 in Figure 3, represents the transport of data in a connectionless, unacknowledged mode of operation. Signaling between a mobile station 12, an access point 36, and the interworking element 44 are represented in the sequence diagram. As the upper-level GPRS layers 10 provide various levels of acknowledgment modes for supporting reliable user data transfer, an acknowledgment mode is not necessary in the WIP layer. Accordingly, the WIP layer provides a relay protocol in which data is not separated by type. That is to 15 say, the WIP layer does not separate LLC PDUs and MM signaling. And, as a result, both are transportable by a UNITDATA PDU. As illustrated in the sequence diagram 114, any downlink MM signaling/PDP is transferable, indicated by the segment 116 between the 20 IWE 44 and the mobile station 12. Thereafter, a WIP UNITDATA message, indicated by the line segment 118, is transmittable by the IWE 44 to the mobile station. The segment 118 represents a downlink transmission. Any uplink MM signaling/PDP is analogously represented 25 by the segment 122. Thereafter, an uplink message forming a WIP UNITDATA message, represented by the segment 124, is transmittable by the mobile station 12 to the IWE. The UNITDATA forming the downlink or uplink transmission is of any selected type, such as a 30 PDU type, a TLLI value, a QoS profile, an IMSI value, an alignment octet, or a LLC-SDU.

To utilize the mobility management provided pursuant to a GPRS system, GPRS location management is

mapped to the integrated system. Here, every WLAN AP is mapped to a GPRS cell. Every AP, thereby, has a unique cell ID number. In the exemplary implementation, mapping is performed at the WIP layer within the IWE 44. The IWE includes a static table which maps every AP ID, e.g., a 48-bit MAC address, to a cell ID.

Figure 4 illustrates a message sequence diagram 126 which represents operation of the integrated communication system portion to perform the functions of identifying a current serving cell ID. The functions performed by the WIP layer are analogous to the operations performed in the GPRS system by which a mobile station selects and identifies its current serving cell by a cell selection and reselection procedure. Analogously, in the integrated communication system portion, the mobile station is capable of moving between access points 36. While moving, the mobile station performs WLAN association, reassociation, and deassociation operations with successive ones of the access points.

The message sequence diagram illustrates signaling between the mobile station 12, and access point 36, and the interworking element 44. WLAN authentication procedures are indicated by the segment 128. Once authentication procedures have been completed, the mobile station sends a MAC association message, indicated by the segment 132, to the access point. Responsive thereto, the access point returns a corresponding MAC association message, here designated by the segment 134. Then, and as indicated by the segment 136, the mobile station sends a WIP cell ID request multicast message, by way of the access point

36 to the interworking element 44. And, responsive thereto, the IWE returns a response message, indicated by the segment 138 to the mobile station. Then, and as indicated by the segment 142, the mobile station
5 passes on the cell ID. The messages indicated by the segments 132-138 correspond with standard WLAN association procedures set forth in the IEEE 802.11 standard.

The messaging represented in the message sequence
10 diagram makes use of the Ethernet multicast and broadcast service by which to define a MAC multicast address for sending a cell ID request PDU to the interworking unit 44. All mobile stations and interworking units 44 in the communication system
15 portion should belong to the multicast group. The access point 36, however, is not required to belong to the multicast group as the access point do not understand the message indicated by the segments 136 and 138. After the interworking element 44 sends the
20 response message 138, the interworking element functions to record the MAC address of the mobile station and the cell ID associated therewith in a converting table. The converting table is used to insert the cell ID to uplink data.

25 The WIP layer of the interworking element knows the MAC address for each WIP PDU received thereat. A mapping table containing the MAC address of the associated mobile station, the cell ID associated therewith, as well as the interworking element, is
30 able to search for the cell ID of the sending mobile station according to the MAC address of the sending mobile station. The interworking element passes the cell ID from which the LLC SDU is associated together

with the LLC SDU to the appropriate LLC layer.
Thereby, analogous to operation in a GPRS system, the
function of the BSS GP layer enables the SGSN to know
from which cell a LLC SDU originates. The location of
5 the mobile station is updated to the SGSN by checking
the cell ID accompanied with the LLC SDU.

The WIP layer further fulfills the requirement
that a TLLI (Temporary Logic Link Identifier) is
transportable from a LLC layer to a lower-level layer.
10 Such transport is performed by encoding the TLLI field
in a UNITDATA PDU, as noted previously with respect to
the messaging indicated with respect to Figure 2.

Paging is also performed pursuant to operation of
the WIP layer. Paging is a basic function of the GPRS
15 system. Figure 5 illustrates a message sequence
diagram, shown generally at 146, and shows the
messaging transported between the mobile station 12
and the interworking element 44 by way of access
points 36. A page message, WIP PAGING, is indicated
20 by the segment 148, sent by the interworking element
to the mobile station 12. Responsive to detection at
the mobile station of the paging message, a WIP-layer
UNITDATA message, utilizing a TLLI is returned to the
interworking element. The message is indicated by the
25 segment 152 shown in the Figure.

The paging procedure provides a manner by which
the interworking element 44 identifies the cell in
which the mobile station is located. If the mobile
station is within the coverage area of the
30 interworking element, the interworking element is
always aware of the cell in which the mobile station
is located by effectuation of the WLAN association and

cell ID inquiry procedure, noted previously. The paging procedure described here with respect to Figure 4 fulfills a GPRS GMM layer requirement.

Figure 6 illustrates a message sequence diagram, shown generally at 156. Again, messaging of signals transported between a mobile station and an interworking element 44, by way of an access point 36, is again represented. In the GPRS system, suspend and resume messages are used by the mobile station to order the LLC layer to suspend, or resume, frame transmission. The WIP layer provides this functionality without necessitating alteration of the LLC layer. A WIP SUSPEND message, indicated by the segment 158, is sent by the mobile station to the interworking element. Responsive thereto, the interworking element returns an acknowledgment message, indicated by the segment 162. Receipt at the interworking element 144 of a SUSPEND PDU indicates that the mobile station wants to suspend its GPRS WLAN integrated service. The acknowledgment response is returned to provide a positive acknowledgment of the suspension.

Figure 7 illustrates a message sequence diagram, shown generally at 166, here representing messaging of signals between the mobile station 12 and the interworking element 44 to resume communications subsequent to a suspension to communication. Here, a WIP RESUME message is generated, indicated by the segment 168, is sent by the mobile station to the interworking element 44. Responsive thereto, the interworking element returns an acknowledgment message, indicated by the segment 172.

By implementing the PDU-based messages described in the preceding figures, the integrated communication system portion is able to support basic packet data service with the speedy WLAN radio part as well as
5 providing wide area mobility management and security pursuant to the GPRS part.

The previous descriptions are of preferred examples for implementing the invention, and the scope of the invention should not necessarily be limited by
10 this description. The scope of the present invention is defined by the following claims.

We claim:

1. In a packet radio communication system for communicating packet data, an improvement of an integrator for integrating operation of a first packet data system having at least a first packet-data-system element with operation of a second packet data system having at least a second packet-data-system element, thereby to form an integrated system of the packet radio communication system, said integrator comprising:

an integration element at least functionally coupled between the first packet-data-system element and the second packet-data-system element, said integration element for relaying packet data between the first packet-data-system element and the second packet-data-system element, the packet data of any selected information-element type of a plurality of element types defined in either of the first packet data system and the second packet data system.

2. The integrator of claim 1 wherein the packet radio communication system comprises a network infrastructure including a first fixed-site transceiver and at least a second fixed-site transceiver with which a mobile station is selectably connectable thereto by way of a radio link and wherein said integration element further maps identities of the first and at least second fixed site transceiver defined in the first packet data system to corresponding identities defined in the second packet data system.

3. The integrator of claim 2 wherein the packet radio communication system further comprises an interworking element (IWE) coupled to the first and at least second fixed site transceivers and wherein a
5 portion of said integrator is embodied at the IWE.

4. The integrator of claim 3 wherein said integration element comprises a memory element forming a table, the table containing the identities of the first and at least second fixed site transceivers
10 defined in the first packet data system and, indexed there against, the identities of the first and at least second fixed site transceivers defined in the second packet data system.

5. The integrator of claim 2 wherein a portion
15 of said integration element is embodied at the mobile station.

6. The integrator of claim 5 wherein the second packet data system comprises a WLAN (Wireless Local Area Network), wherein the first fixed-site
20 transceiver and the at least second fixed-site transceiver comprise access points of the WLAN, and wherein the mobile station, at which a portion of said integration element is embodied, performs association operations selectably to form radio links with the
25 access points.

7. The integrator of claim 6 wherein the packet radio communication system further comprises an interworking element (IWE) coupled to the first and at least second fixed-site transceivers and an Ethernet
30 connection for coupling said IWE thereto and wherein the mobile station, at which a portion of said integration element is embodied, further performs cell

identification request operations selectably to identify the mobile station to the IWE.

8. The integrator of claim 7 wherein the cell identification request operations further associate
5 the mobile station with a cell identifier, the cell identifier defined pursuant to the first packet data system.

9. The integrator of claim 8 wherein said IWE further comprises a table, the table for storing
10 indications of a n identity of the mobile station and the cell identifier, the cell identifier indexed against the identity of the mobile station.

10. The integrator of claim 9 wherein the mobile station is identified by a MAC address.

15 11. The integrator of claim 10 wherein the first packet-data-system element comprises a LLC logic layer and wherein said integration element further transports a Temporary Logic Link Identifier (TLLI) between the LLC logic layer and the second packet-
20 data-system element.

12. The integrator of claim 11 wherein said integration element further generates a page message to page the mobile station, the page message generated at an access point corresponding to the cell
25 identifier identified in the table formed at said IWE.

13. The integrator of claim 12 wherein the portion of said integration element located at the mobile station responds to the page message with a response message, the response message including
30 indications of the TLLI, the TLLI identifying the mobile station.

14. The integrator of claim 12 wherein the portion of said integration element located at the mobile station further selectably transmits a communication suspend message to the IWE, the
5 communication suspend message for requesting suspension of communication of data to the mobile station.

15. The integrator of claim 14 wherein the portion of said integration element located at the
10 mobile station further selectably transmits a communication resume message to the IWE, the communication resume message for requesting resumption of communication of data to the mobile station.

16. In a method for communicating packet data in
15 a radio communication system having a network infrastructure including a first fixed-site transceiver and at least a second fixed-site transceiver with which a mobile station is selectably connectable by way of a radio link, an improvement of
20 a method for integrating operation of a first packet data system having at least a first packet-data-system element with operation of a second packet data system having at least a second packet-data-system element, thereby to form an integrated system of the packet
25 radio communication system, said method comprising:

mapping identities of the first and at least second fixed-site transceivers defined in the first packet data system to corresponding identities defined in the second packet data system;

30 relaying packet data between the first packet-data-system element and a selected one of the first and at least second fixed-site transceivers, the packet data of any selected information-element type

of a plurality of element types defined in either of the first packet data system and the second packet data system.

17. The method of claim 16 wherein said
5 operation of mapping comprises:

indexing the identities of the first and at least second fixed site transceivers defined in the first packet data system against the identities of the first and at least second fixed-site transceivers
10 defined in the second packet data system.

18. The method of claim 17 wherein said operation of relaying comprises accessing the identities of the first and at least second fixed-site transceivers indexed during said operation of
15 indexing, thereby to identify the first and second fixed-site transceivers in terms of a selected one of the first and second packet data systems.

19. In a packet radio communication system defined in terms of local layers, an improvement of an
20 integrator for integrating operation of a first packet data system having at least a first packet-data-system local layer and a second packet data system having at least a second packet-data-system logical layer, said integrator comprising:

25 an integration logical layer logically positioned between the first packet-data-system logical layer and the second packet-data-system logical layer, said integration logical layer for relaying packet data between the first packet-data-
30 system logical layer and the second packet-data-system logical layer, the packet data of any selected

information-element type of a plurality of element types defined in either of the first packet data system and the second packet data system.

20. The integrator of claim 19 wherein the first
5 packet data system comprises a GPRS (General Packet
Radio Service) system, wherein the second packet data
system comprises an IEEE 802-11 standard-compliant
WLAN (Wireless Local Area Network) system and wherein
said integration logical layer comprises a WLAN
10 integration protocol layer layered above a logical
layer of the IEEE 802.11 standard-compliant WLAN
system and layered beneath a logical layer of the GPRS
system.
